The newly described species *Astragalus gulemiensis* Sytin et Pospelov (sect. *Komaroviella*) was discovered near the Gulemi River mouth, on shingle beds shoreline of Ayan Lake, at an altitude of 473 m a. s. l., on the territory of the Putorana Nature Reserve. This species is related to *A. schumilovae* Polozhij (Evenkiysky municipal area, Podkamennaya Tunguska River basin), but differs significantly from the latter by inflorescence structure, namely flowers on pedicels 4–7 mm long, as well as pods cylindrical, linear, falciform, ascending or erect, densely black and white-pilose, corolla with mauve-pink standard lamina, and pale violet wings and keel. Both species are obviously relict and need protection.

*Keywords:* *Astragalus gulemiensis*, section *Komaroviella*, Fabaceae, new species, Putorana Plateau.

#### ACKNOWLEDGEMENTS

The authors thank D.D. Slastunov for the photo of the type specimens.

The study was carried out within the framework of the institutional research project of the Komarov Botanical Institute RAS “Vascular plants of Eurasia: systematics, flora, plant resources” (№ AAAA-A19-119031290052-1).
